(April 2026)

Abstract

The Customer Feedback Analysis System is a Java-based application developed to analyze and interpret customer reviews efficiently using Object-Oriented Programming (OOP) concepts. In today's digital environment, businesses receive a large volume of feedback in the form of ratings and comments, making manual analysis time-consuming and inefficient. This system automates the process by collecting multiple customer feedback entries, each consisting of a numerical rating and a textual comment.

The application uses a Feedback class to represent individual reviews and an Analyzer class to process the data. The system calculates the average rating from all feedback entries and categorizes the overall customer opinion into four levels: Excellent, Good, Average, and Poor. This classification is performed using switch-case logic, ensuring structured decision-making. The project demonstrates key programming concepts such as classes, objects, encapsulation, arrays, and control statements. It provides a simple yet effective solution for understanding customer satisfaction trends. The system can be further enhanced with advanced features like real-time data input, database integration, and graphical user interfaces, making it more scalable and practical for real-world applications.

Introduction

In today's digital world, customer feedback is an important factor for improving products and services. Businesses receive large amounts of feedback in the form of ratings and comments, which makes manual analysis difficult, time-consuming, and sometimes inaccurate. To overcome this problem, the Customer Feedback Analysis System is developed using Java and Object-Oriented Programming (OOP) concepts.

This system helps in collecting and analyzing multiple customer feedback entries efficiently. Each feedback consists of a rating score and a comment, which are stored using objects. The system then processes all feedbacks to calculate the average rating and determines the overall customer opinion. Based on the average score, the feedback is categorized into Excellent, Good, Average, or Poor using switch-case logic.

The project demonstrates the use of classes, objects, arrays, and decision-making techniques. It reduces manual effort and provides a simple and effective way to understand customer satisfaction levels.

Scope

This project is suitable for small libraries and can be extended with database integration in future.

System Requirements

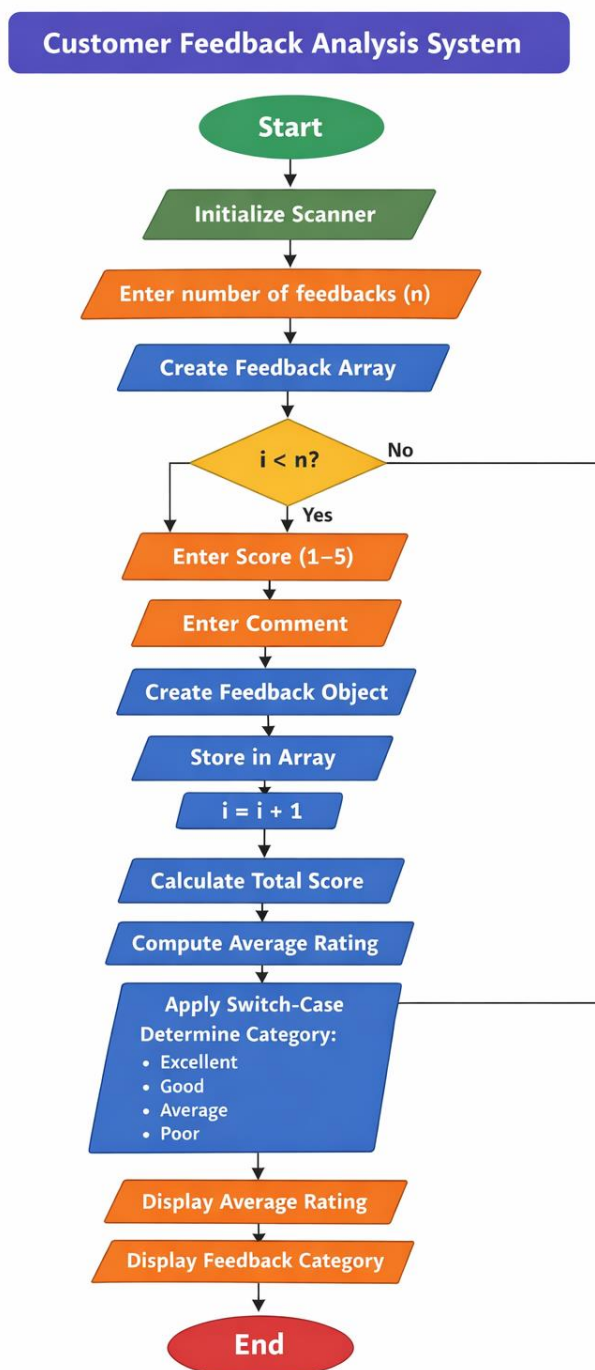

Hardware: Computer with 4GB RAM

Software: Java JDK, IDE (VS Code/Eclipse/Edit Plus)

Methodology

Explain how your project works like first we add something, then search, then modify etc.

Flowchart

CLASS NAME

Variables inside class

o Methods inside class

o If array is present within the class also mention it here

Implementation

Explain different classes used in your program(only explain logic don't paste code here)

Sample Input/Output

Paste screenshot of your terminal with different operations

Future Enhancements

Things you can improve on your project

Gantt Chart

1. Planning & Structure

A Gantt chart helps you break the project into tasks (design, coding, testing, etc.) and set timelines.

Even if it's already built once, rebuilding or modifying still needs planning.

2. Time Management

It shows:

- When each task starts
- When it should finish
- This helps avoid delays and last-minute panic.

Conclusion

The project successfully demonstrates Java OOP concepts and provides a functional system.
